

NAME:SIRIVELLA SANJANA

ROLLNO:2403A510D4

BATCHNO: 05

COURSE:AI ASSISSTED CODING .

**Task-1:AskAltogenerateaFlaskRESTAPIwithoneroute: GET
/hello → returns {"message": "Hello, AI Coding!"}**

PROMPT:

"Generate a simple Flask REST API in Python. The API should have a single endpoint: GET /hello . When this endpoint is accessed, it must return a JSON response with the following structure: {"message": "Hello, AI Coding!"} . Please include comments in the code and instructions on how to run the application."

CODE:

```
1 # app.py
2 from flask import Flask, jsonify
3
4 # Initialize the Flask application instance
5 app = Flask(__name__)
6
7 @app.route('/hello', methods=['GET'])
8 def get_hello_message():
9     """
10     Defines the endpoint for GET /hello.
11     Returns a static JSON message.
12     """
13     # Create a Python dictionary for the response
14     message = {
15         "message": "Hello, AI Coding!"
16     }
17     # Use Flask's jsonify to convert the dictionary to a JSON response
18     return jsonify(message)
19
20 # This block allows the script to be run directly
21 # The server will only run if this file is executed as the main program
22 if __name__ == '__main__':
23     # Run the app in debug mode for development
24     # It will listen on http://127.0.0.1:5000 by default
25     app.run(debug=True)
```

OUTPUT:

OBSERVATION:

- **Simplicity and Readability:** It uses standard Flask decorators (`@app.route`) to clearly map a URL endpoint to a Python function.
- **Correct JSON Handling:** It correctly uses the `jsonify` utility from Flask. This is important because `jsonify` not only converts a Python dictionary to a JSON string but also sets the correct `Content-Type` header to `application/json`, which is the standard for REST APIs.
- **Standard Structure:** The `if __name__ == '__main__':` block is a standard Python convention that makes the script reusable and prevents the server from running if the file is imported into another module.
- **Extensibility:** This simple file serves as an excellent foundation. You can easily add more routes by defining new functions with their own `@app.route` decorators, connect to a database, or add more complex business logic.

Task-2:

UseAltobuildRESTendpointsforaStudentAPI:

- GET/students→Listallstudents.
- POST/students→Addanewstudent.
- PUT/students/<id>→Updatestudentdetails.
- DELETE/students/<id>→Deleteastudent.

Expected Output:

- FlaskAPIwithdictionary/list storage.
- JSONresponsesforeachoperation

Prompt:

"Generate a complete Flask REST API to manage a collection of students. The student data should be stored in-memory using a Python list of dictionaries.

Please implement the following four endpoints:

1. **GET /students** : Returns a JSON array of all students.
2. **POST /students** : Accepts a JSON object like `{"name": "New Student", "major": "Computer Science"}`. It should generate a new unique ID, add the student to the list, and return the complete student object (including the new ID) with a **201 Created** status code.
3. **PUT /students/<int:student_id>** : Finds a student by their ID. It should update the student's data with the provided JSON payload and return the updated student object. If the student ID is not found, it should return a 404 error with a message.
4. **DELETE /students/<int:student_id>** : Finds a student by their ID and removes them from the list. It should return a success message. If the student ID is not found, it should return a 404 error.

Code:

```
1 # app.py
2 from flask import Flask, jsonify, request
3
4 # Initialize the Flask application instance
5 app = Flask(__name__)
6
7 # In-memory data store (simulating a database)
8 students = [
9     {"id": 1, "name": "Alice", "major": "Physics"},
10    {"id": 2, "name": "Bob", "major": "Chemistry"}
11 ]
12 # A simple counter to generate unique IDs for new students
13 next_id = 3
14
15 @app.route('/students', methods=['GET'])
16 def get_students():
17     """
18     GET /students
19     Returns the list of all students.
20     """
21     return jsonify(students)
22
23 @app.route('/students', methods=['POST'])
24 def add_student():
25     """
26     POST /students
27     Adds a new student to the list.
28     """
29     global next_id
30     if not request.json or 'name' not in request.json or 'major' not in request.json:
31         return jsonify({"error": "Missing name or major in request body"}), 400
32     # Add new student logic would go here
```

```

33     new_student = {
34         "id": next_id,
35         "name": request.json['name'],
36         "major": request.json['major']
37     }
38     students.append(new_student)
39     next_id += 1
40     return jsonify(new_student), 201 # 201 Created
41
42 @app.route('/students/<int:student_id>', methods=['PUT'])
43 def update_student(student_id):
44     """
45     PUT /students/<id>
46     Updates an existing student's details.
47     """
48     student = next((s for s in students if s['id'] == student_id), None)
49     if student is None:
50         return jsonify({"error": "Student not found"}), 404
51
52     # Update fields if they exist in the request JSON
53     student['name'] = request.json.get('name', student['name'])
54     student['major'] = request.json.get('major', student['major'])
55
56     return jsonify(student)
57
58 @app.route('/students/<int:student_id>', methods=['DELETE'])
59 def delete_student(student_id):
60     """
61     DELETE /students/<id>
62     Deletes a student from the list.
63     """

```

```

61     DELETE /students/<id>
62     Deletes a student from the list.
63     """
64     global students
65     student = next((s for s in students if s['id'] == student_id), None)
66     if student is None:
67         return jsonify({"error": "Student not found"}), 404
68
69     # Re-create the list excluding the student to be deleted
70     students = [s for s in students if s['id'] != student_id]
71     return jsonify({"message": f"Student with id {student_id} deleted successfully"})
72
73 # This block allows the script to be run directly
74 # The server will only run if this file is executed as the main program
75 if __name__ == '__main__':
76     # Run the app in debug mode for development
77     # It will listen on http://127.0.0.1:5000 by default
78     app.run(debug=True, port=5000)
79

```

Output:

```
← 127.0.0.1:5000/students
Pretty-print ☐
[
  {
    "id": 1,
    "major": "Physics",
    "name": "Alice"
  },
  {
    "id": 2,
    "major": "Chemistry",
    "name": "Bob"
  }
]
```

Observation:

- **RESTful Principles:** The code correctly uses HTTP methods (GET, POST, PUT, DELETE) to represent actions on the students resource. The URL structure is clean and follows standard conventions.
- **State Management:** It uses a simple global list (students) and a counter (next_id) for in-memory storage, which is perfect for a self-contained demo.
- **Error Handling:** The code includes essential error handling, such as returning a 404 Not Found status when an ID doesn't exist and a 400 Bad Request if the POST payload is malformed. This makes the API more reliable.
- **Correct HTTP Status Codes:** It correctly returns 201 Created for a successful POST operation, which is a key detail in REST API design, signaling that a new resource was created.
- **Readability and Maintainability:** The code is well-commented, with each function having a docstring that explains its purpose and the endpoint it serves. This makes it easy to understand and extend.

Task-3:AskAltogenerateaRESTAPIendpoint Expected

Output:

Workingsearchfunctionwithqueryparamhandling. Prompt:

"Please extend the existing Flask REST API for students by adding a new search endpoint.

The new endpoint should be: **GET /students/search**

It must accept a URL query parameter named **q**. The endpoint should perform a case-insensitive search and return a JSON list of all students where the search term is found in either the student's **name** or **major**.

If the **q** parameter is missing or empty, or if no students match the search, it should return an empty JSON array **[]**.

Please provide the updated code and a **curl** example to test the search functionality."

Code:

```
1  # app.py
2  from flask import Flask, jsonify, request
3
4  # Initialize the Flask application instance
5  app = Flask(__name__)
6
7  # In-memory data store (simulating a database)
8  students = [
9      {"id": 1, "name": "Alice", "major": "Physics"},
10     {"id": 2, "name": "Bob", "major": "Chemistry"}

57
58 @app.route('/students/<int:student_id>', methods=['PUT'])
59 def update_student(student_id):
60     """
61     PUT /students/<id>
62     Updates an existing student's details.
63     """
64     student = next((s for s in students if s['id'] == student_id), None)
65     if student is None:

```

```

65     if student is None:
66         return jsonify({"error": "Student not found"}), 404
67
68     # Update fields if they exist in the request JSON
69     student['name'] = request.json.get('name', student['name'])
70     student['major'] = request.json.get('major', student['major'])
71
72     return jsonify(student)
73
74 @app.route('/students/<int:student_id>', methods=['DELETE'])
75 def delete_student(student_id):
76     """
77     DELETE /students/<id>
78     Deletes a student from the list.
79     """
80     global students
81     student = next((s for s in students if s['id'] == student_id), None)
82     if student is None:
83         return jsonify({"error": "Student not found"}), 404
84
85     # Re-create the list excluding the student to be deleted
86     students = [s for s in students if s['id'] != student_id]
87     return jsonify({"message": f"Student with id {student_id} deleted successfully"})
88
89 # This block allows the script to be run directly
90 # The server will only run if this file is executed as the main program
91 if __name__ == '__main__':
92     # Run the app in debug mode for development
93     # It will listen on http://127.0.0.1:5000 by default
94     app.run(debug=True, port=5000)
95

```

Output:

Observation:

- **Query Parameter Handling:** The code correctly uses `request.args.get('q', '')` to safely retrieve the query parameter. This method is robust because it doesn't raise an error if the `q` parameter is missing; instead, it defaults to an empty string.
- **Case-Insensitive Search:** The implementation correctly converts both the search query and the student data (`name`, `major`) to lowercase before comparison, ensuring the search is case-insensitive as requested.
- **Efficient Filtering:** A list comprehension (`[s for s in students if ...]`) is used to filter the data. This is a concise and highly "Pythonic" way to create a new list based on a condition, making the code readable and efficient for in-memory data.
- **RESTful Design:** The new endpoint `GET /students/search` is a good design choice. It clearly separates the action of searching from fetching the entire collection (`GET /students`), which is a common and clean pattern in REST API design.

Task-4: Ask AI to write test scripts using Python requests module to call APIs created above.

Prompt:

"Write a Python script to test the Flask Student API. The script must use the `requests` library to make HTTP calls to a locally running server at `http://127.0.0.1:5000`.

Code:

```

1  # test_api.py
2  import requests
3  import json
4
5  # The base URL for the API, assuming it's running locally on port 5000
6  BASE_URL = "http://127.0.0.1:5000"
7
8  def run_tests():
9      """
10     Executes a sequence of API tests for the Student API.
11     """
12     print("--- Starting API Integration Tests ---")
13
14     # This will store the ID of the student we create
15     new_student_id = None
16
17     try:
18         # 1. GET /students: Fetch initial list
19         print("\n[TEST 1] GET /students - Fetching all students...")
20         response = requests.get(f"{BASE_URL}/students")
21         assert response.status_code == 200
22         initial_students = response.json()
23         assert len(initial_students) == 2
24         print("PASS: Initial student list fetched successfully.")
25
26         # 2. POST /students: Add a new student
27         print("\n[TEST 2] POST /students - Adding a new student...")
28         new_student_data = {"name": "David", "major": "Mathematics"}
29         response = requests.post(f"{BASE_URL}/students", json=new_student_data)
30         assert response.status_code == 201
31         created_student = response.json()

))
Please ensure the Flask API server is running.

```

Observation:

- **Clarity and Structure:** The script is organized into a clear, sequential flow. Each test step is announced with a `print` statement, making the output easy to follow.
- **Use of `requests`:** It correctly uses the `requests` library's methods (`get`, `post`, `put`, `delete`) and passes JSON data where required.
- **Assertions:** The use of `assert` is a standard and effective way to verify test outcomes. It checks for correct HTTP status codes and validates the content of the JSON responses, immediately halting the script if a condition is not met.
- **State Management:** The script correctly handles the stateful nature of the API by capturing the `id` of the newly created student and using it in subsequent `PUT` and `DELETE` requests.
- **Covers Success and Failure:** It tests the "happy path" (creating, updating, deleting successfully) as well as important error cases (verifying deletion, attempting to update a non-existent record), making the test suite more robust.
- **Practicality:** This script is a practical, real-world example of how developers write automated tests to ensure their APIs function as expected, preventing regressions when new features are added or code is refactored.
